Spectrums of DFT

- > Models capturing psychophysical data
- Models capturing behavioral competences
- > Models capturing intentional agents?

Intentionality

"The capacity of the nervous system to generate mental states that are 'about' things in the world."

- How may intentional states emerge from neural processes?
- How are intentional states stabilized in time?
- Under which circumstances are intentional states destabilized?

Intentional States

> Defined through a **content** and a **psychological mode**

World-to-Mind Direction of Fit

- > I am picking a *red flower* in front of me
- > I will pick a *red flower* later in the park
- ➢ I want a red flower

Mind-to-World Direction of Fit

- ➤ I am seeing a red flower in front of me
- > I recall a *red flower* growing in the park
- ➤ I believe *red flowers* have a green stem

(Intention-in-Action) (Prior Intention) (Desire)

(Perception)

(Memory)

(Belief)

content

[Searle,1983]

Directions of Fit: Mind-to-World

Example: Perception

Example: Intention-In-Action

A neural Process Model

- Detects CoS based on sensor information
- Represents action initiation and termination
- Drives motor behavior

[Sandamirskaya and Schöner, 2010]

Condition of Satisfaction Network

A simple Toy Scenario

- Scenario includes six different psychological modes
- Behavior emerges from autonomous transitions between intentional states
- Stabilized intentional states make up experience
- Experience allows the formation of categorical beliefs

[Tekülve and Schöner, 2019]

Mind-To-World States

> Perception

- See Objects (Position, Height, Color)
- Observe Color Change
- Sense Location, Arm , Paint-Device Status

> Memory

- Objects in World Space
- ≻ Belief
 - Paint Rules:
 Coat Color + Canvas Color = Result Color

World-to-Mind States

Intention-in-Action

- Move in 1-D Space
- Reach for Objects
- Pick-Up/Dispense Color
- Invoke certain Mind-to-World States

> Prior Intention

- Locate an Object
- Collect a certain Coat
- Apply Coat on a certain Canvas
- > Desire
 - Create a certain color

Architecture Overview

From Sensor to Field

Prior Intentions

Collecting Sequence

Autonomous Learning

> Requirements

- Autonomous Action
- Meaningful Experience

> Problems:

- Content Abstraction
- Temporal Organization

Beliefs

Learning from a single episode

Cued activation to guide behavior

CoatCanvasResult \frown \leftarrow \frown \frown \frown \leftarrow \frown \frown \frown \frown \bullet \frown \frown \bullet \bullet

Rejection in the face of conflicting evidence

Belief Architecture

Belief Recall and Rejection

Conclusion

- From the sensorimotor surface to abstract representations
- Process models of different psychological modes
- Autonomous learning requires infrastructure
